

# Lecture 27: Using LT to solve Initial Value Problems

27-1

## ① Goal of this lecture

Recall the goal announced in Lec. 26:

Instead of solving an IVP using DE-solving techniques studied in earlier Chapters, we will solve it in a round-about way.

IVP to be solved:

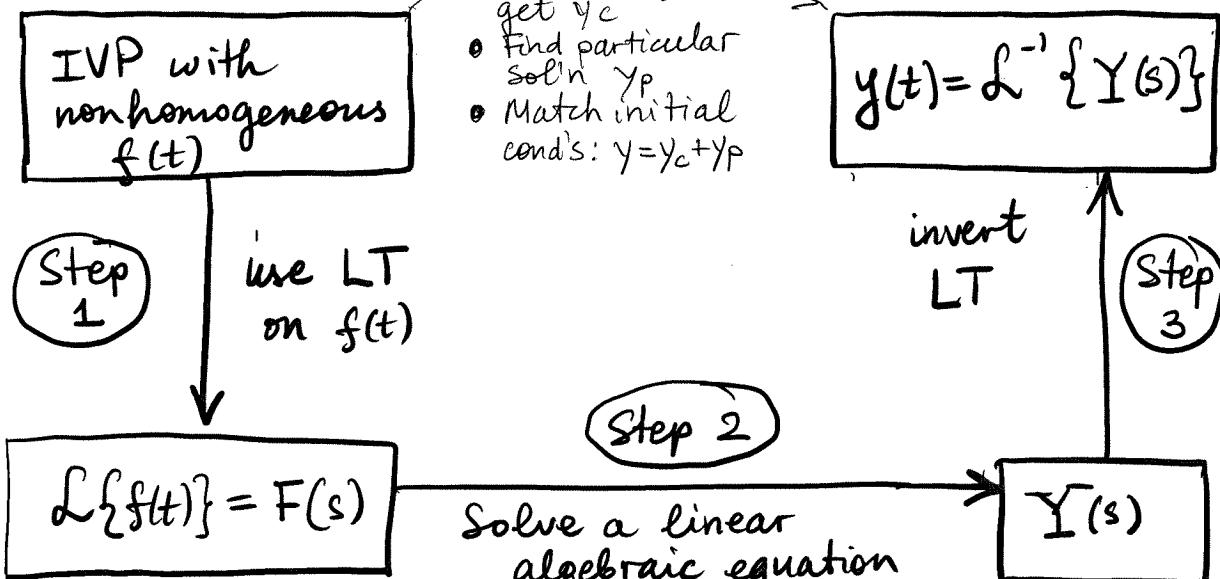

$$\begin{cases} \text{"homogeneous DE for } y(t) = f(t) \\ \text{Initial Conditions for } y(t_0) \end{cases}$$

To be consistent with notations in the book, switch from "g(t)" to "f(t)" for the nonhomogeneous term.

Before:

- Solve homog. DE, get  $y_c$
- Find particular sol'n  $y_p$
- Match initial cond's:  $y = y_c + y_p$

$$y(t) = \mathcal{L}^{-1}\{Y(s)\}$$

$$\text{to get: } Y(s) = \underbrace{\Phi(s)}_{\text{from homogeneous DE}} \left( \underbrace{F(s)}_{\text{from } f(t)} + \underbrace{I(s)}_{\text{from Initial cond's}} \right)$$

from homogeneous DE      from  $f(t)$       from Initial cond's

So, to develop this new method of solving a nonhomogeneous DE, we will:

For Step 1) Continue learning about L.T.;

For Step 2) Learn how to find  $\Phi(s)$  and  $I(s)$  above;

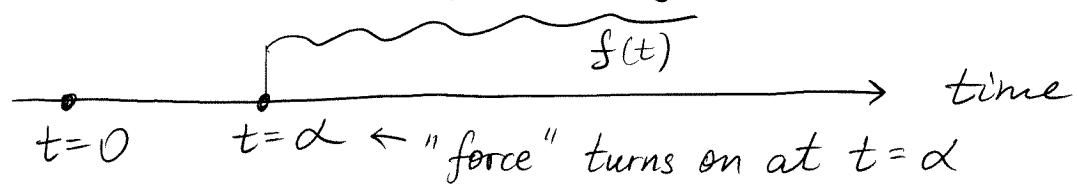

For Step 3) Review how to invert LT

(we already did one example of  $y(t) = \mathcal{L}^{-1}\{Y(s)\}$  in Ex. 2 of Lec. 26.)

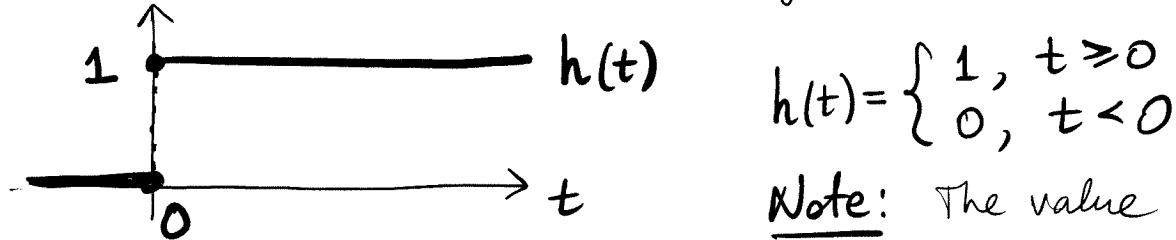

### ① For Step 1

#### 1a) The Heavyside step-function

In some applications, one has the nonhomogeneous terms that can begin acting after the initial time:

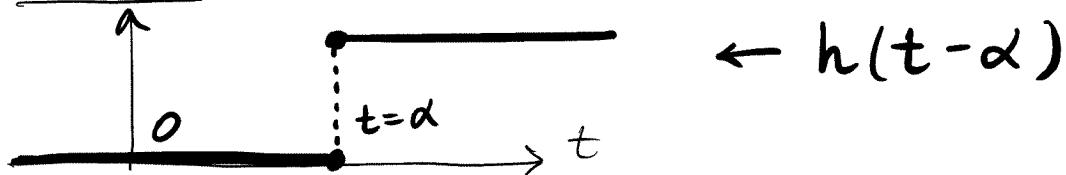

To describe this, use the Heavyside step-function:

Note: The value

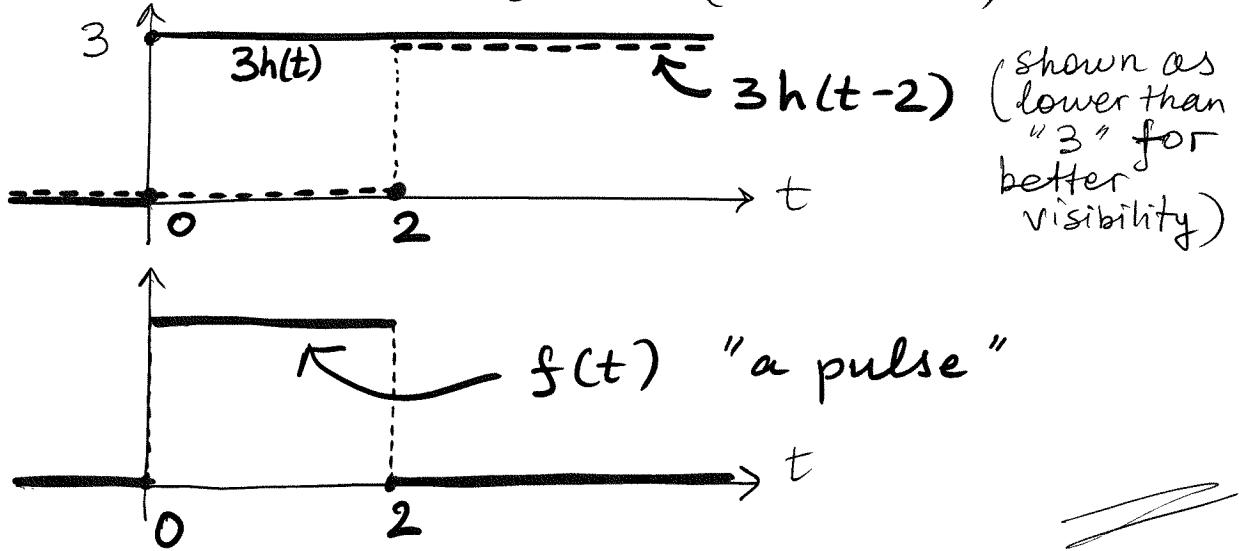

at a single point,  $t=0$ ,  
is not important.

#### Ex. 1(a)

27-3

Ex. 1(b) Find  $f(t) = 3(h(t) - h(t-2))$

Let us now find  $\mathcal{L}\{h(t)\}$ :

$$\mathcal{L}\{h(t)\} = \int_0^\infty e^{-st} \cdot \underset{\substack{\uparrow \\ h(t) \text{ for } t > 0}}{1} dt = \frac{e^{-st}}{-s} \Big|_0^\infty =$$

$$= \frac{e^{-s \cdot 0} - e^{-s \cdot \infty}}{-s} = \frac{1}{s}$$

↑  
See Ex. 1/Lec. 26  
or Ex. 2/Sec. 5.1  
for a more  
accurate treatment

Note 1 : This appears to be the same answer as  $\mathcal{L}\{1\}$  (see Ex. 1(a) in Lec. 26 (with  $a=0$ ) or the Table on p. 340-341 in the book). This is expected, since LT only "cares about"  $t > 0$ , where  $h(t) = 1$ .

Note 2 : The real utility of  $h(t)$  is to describe processes that start at  $t = \alpha > 0$ , and so let's find  $\mathcal{L}\{h(t-\alpha)\}$ .

27-4

$$\begin{aligned} \mathcal{L}\{h(t-\alpha)\} &= \int_0^\infty e^{-st} h(t-\alpha) dt = \xleftarrow{\text{assume } \alpha > 0} \\ &\int_0^\alpha e^{-st} \cdot 0 dt + \int_\alpha^\infty e^{-st} \cdot 1 \cdot dt = \int_\alpha^\infty e^{-st} dt = \\ &= \int_\alpha^\infty e^{-s[(t-\alpha)+\alpha]} dt = e^{-\alpha s} \int_\alpha^\infty e^{-s(t-\alpha)} dt \\ &\xleftarrow{\text{trick to be repeatedly used below}} \end{aligned}$$

$$\begin{aligned} u &= t - \alpha \\ t: \alpha &\rightarrow \infty \\ u: 0 &\rightarrow \infty \\ du &= dt \end{aligned}$$

Thus:

$$\boxed{\mathcal{L}\{h(t-\alpha)\} = \frac{e^{-\alpha s}}{s}}$$

**1b** LT of  $e^{at}$ ,  $t^n$ ,  $\sin wt$ ,  $\cos wt$

The first one was done in Ex. 1(a) in Lec. 26;

the rest are done on pp. 330-331 in the book.

(Also,  $\mathcal{L}\{t^n\}$  was done in Ex. 1(b) in Lec. 26.)

They are all done via integration by parts.

See Table on pp. 340-341; you will need LT of  $h(t)$ ,  $e^{at}$ ,  $t^n$ ,  $\sin$ ,  $\cos$  for HW & Final Exam, but you are not required to remember any of them.

**Must also see Ex. 1 / Sec. 5.2** for some representative cases.

### 1c Shift Theorems

Under the usual conditions on  $f(t)$  when all the LT's below exist (see Lec. 26, topic ④ = Thm. 5.1), one has:

#### Theorem 5.4 (a)

$$\mathcal{L}\{e^{\alpha t} f(t)\} = F(s-\alpha) \quad \left\{ \begin{array}{l} \text{equivalently:} \\ e^{\alpha t} \underbrace{f(t)}_{= \mathcal{L}^{-1}\{F(s)\}} = \mathcal{L}^{-1}\{F(s-\alpha)\} \end{array} \right.$$

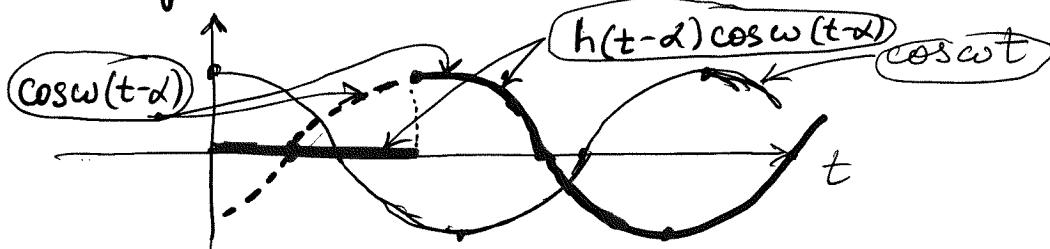

#### Theorem 5.4 (b)

$$\mathcal{L}\{h(t-\alpha) f(t-\alpha)\} = e^{-\alpha s} F(s) \quad \left\{ \begin{array}{l} \text{Equivalently:} \\ h(t-\alpha) \underbrace{f(t-\alpha)}_{\text{where } f(t) = \mathcal{L}^{-1}\{F(s)\}} = \mathcal{L}^{-1}\{e^{-\alpha s} F(s)\} \end{array} \right.$$

See proofs of both (a) & (b) in the book (optional); the proof of (b) is analogous to the proof in Note 2 on pp. 27-3, 27-4 above.

Note 1 = Clarification about the difference between  $h(t-\alpha)f(t-\alpha)$  &  $f(t-\alpha)$ :

- $f(t-\alpha)$  is a shifted copy of  $f(t)$ ; in general,  $f(t-\alpha) \neq 0$  for  $0 < t < \alpha$ .
- $h(t-\alpha)f(t-\alpha)$  is a shifted copy of  $f(t)$  which begins at  $t=\alpha$ ;  $h(t-\alpha)f(t-\alpha) \equiv 0$  for  $0 < t < \alpha$ .

Note 2 = "do not invent your own formulas"

We know from Thm. 5.2 (Lec. 26, topic ⑤) that

$$\mathcal{L}\{c_1 f_1(t) + c_2 f_2(t)\} = c_1 \mathcal{L}\{f_1(t)\} + c_2 \mathcal{L}\{f_2(t)\}.$$

$\nwarrow$  const  $\uparrow$

But:  $\mathcal{L}\{f(t)g(t)\} \neq \mathcal{L}\{f(t)\} \mathcal{L}\{g(t)\}$

and similarly,

$$\mathcal{L}^{-1}\{F(s)G(s)\} \neq \mathcal{L}^{-1}\{F(s)\} \mathcal{L}^{-1}\{G(s)\}$$

E.g., from Thm. 5.4(a):

$$\mathcal{L}\{e^{at}f(t)\} = F(s-a) \neq \mathcal{L}\{e^{at}\} \mathcal{L}\{f(t)\} \left(= \frac{1}{s} \cdot F(s)\right).$$

A more complicated (and interesting!) relation between  $\mathcal{L}\{fg\}$  &  $\mathcal{L}\{f\}$ ,  $\mathcal{L}\{g\}$  does exist, but we won't have the time to learn it (Sec. 5.6, Thm. 5.7).

Note 3: The Shift Theorems allow us to expand the Table on pp. 340-341; see entries 9-12 & 15 there and also Ex. 2 / Sec. 5.2.

Ex. 2(a) Find  $\mathcal{L}\{h(t-3)\cos 4(t-3)\}$ .

$$\mathcal{L}\{h(t-3)\cos 4(t-3)\} \stackrel{\substack{\uparrow \\ \text{Thm. 5.4(B)}}}{=} e^{-3s} \cdot \mathcal{L}\{\cos 4t\} \stackrel{\substack{\uparrow \\ \text{Table}}}{=} e^{-3s} \cdot \frac{s}{s^2 + 4^2}$$

(Recall Note 1 above:  $\mathcal{L}\{h(t-3)\cos 4(t-3)\} \neq \mathcal{L}\{\cos 4(t-3)\}$  !

The latter needs to be found from  $\cos(t-12) = \cos 4t \cos 12 + \sin 4t \sin 12$ )

27-7

Ex. 2(b) Find  $\mathcal{L}^{-1} \left\{ \frac{e^{-s}}{s^2 + 4} \right\}$

In  $e^{-\alpha s}$ ,  $\alpha = 1$ ; the expression looks like Thm. 5.4(b).

So:  $\mathcal{L}^{-1} \left\{ \frac{e^{-1 \cdot s}}{s^2 + 4} \right\} = h(t-1) f(t-1)$ , where

$$f(t) = \mathcal{L}^{-1} \left\{ \frac{1}{s^2 + 4} \right\} \stackrel{\substack{\uparrow \\ \text{Table}}}{=} \mathcal{L}^{-1} \left\{ \frac{1}{2} \cdot \frac{2}{s^2 + 2^2} \right\} = \frac{1}{2} \sin 2t$$

So,  $f(t-1) = \frac{1}{2} \sin 2(t-1)$ ; Answer:  $h(t-1) \cdot \frac{1}{2} \sin 2(t-1)$ . //

Ex. 2(c) Find  $\mathcal{L}^{-1} \left\{ \frac{e^{-s}}{(s-3)^2 + 4} \right\}$ .

This =  $h(t-1) f(t-1)$ , where  $f(t) = \mathcal{L}^{-1} \left\{ \frac{1}{(s-3)^2 + 4} \right\} = e^{3t} \cdot \mathcal{L}^{-1} \left\{ \frac{1}{s^2 + 4} \right\} \stackrel{\substack{\uparrow \\ \text{Thm. 5.4(a)}}}{=} e^{3t} \cdot \frac{1}{2} \sin 2t$ .  $\stackrel{\uparrow}{\text{Ex. 2(b)}}$

Answer:  $h(t-1) \cdot \frac{1}{2} e^{3(t-1)} \sin 2(t-1)$  //

MUST also READ Ex. 2 in textbook (Sec. 5.2).

## ② For Steps 2 & 3 (see p. 27-2)

To take LT of a DE, we need:

Thm. 5.5 Assuming that all the LTs below exist:

(a)  $\mathcal{L} \{ y'(t) \} = s \cdot \mathcal{L} \{ y(t) \} - y(0) \equiv s \cdot Y(s) - y(0)$

(b)  $\mathcal{L} \{ y''(t) \} = s^2 Y(s) - s y(0) - y'(0)$

(will not need part (c) from the textbook).

27-8

Proof of (a): Integrate by parts ↴

$$\begin{aligned} \mathcal{L}\{y'(t)\} &= \int_0^\infty e^{-st} \underbrace{y'(t)}_{g' f'} dt = \underbrace{\int_a^b g f' dt}_{\int_a^b g f' dt = gf \Big|_a^b - \int_a^b g' f dt} \\ &= e^{-st} \cdot y(t) \Big|_0^\infty - \int_0^\infty (\cancel{e^{-st}}) \cdot \underbrace{y(t) dt}_{f} \quad \cancel{\int_a^b g f' dt} \\ &= \cancel{e^{-\cancel{st}} y(\infty)}_0 - \cancel{e^{-\cancel{st}} y(0)}_1 + s \int_0^\infty e^{-st} y(t) dt \\ &= s Y(s) - y(0). \end{aligned}$$

Proof of (b):  $\mathcal{L}\{y''(t)\} = \mathcal{L}\{(y')'\} =$

see p. 334  
(a 1-liner) → { Apply part (a)  
twice. }

Ex. 3(a) (= simplified Ex. 3/book, so also See Ex. 3/book)

Solve the IVP:  $y' - 3y = 6^{f(t)}, y(0) = 5.$

Sol'n: 1)  $\mathcal{L}\{y' - 3y\} = \mathcal{L}\{6\} = 6 \cdot \mathcal{L}\{h(t)\}$

$$\mathcal{L}\{y'\} - 3\mathcal{L}\{y\} = 6 \cdot \frac{1}{s} \quad \text{Table}$$

↑ See Note 1  
after Ex. 1

$$(sY(s) - y(0)) - 3Y(s) = \frac{6}{s}$$

$$(s-3)Y(s) = \frac{6}{s} + y(0)^5$$

$$Y(s) = \frac{1}{s-3} \cdot \left( \frac{6}{s} + 5 \right)$$

See the diagram on  
p. 27-1.

27-9

2) We now need to find  $y(t) = \mathcal{L}^{-1}\{Y(s)\}$ .

$$\mathcal{L}^{-1}\{Y(s)\} = \underbrace{\mathcal{L}^{-1}\left\{\frac{1}{(s-3)} \cdot \frac{6}{s}\right\}}_{\text{1st term}} + \underbrace{\mathcal{L}^{-1}\left\{\frac{1}{s-3} \cdot 5\right\}}_{\text{2nd term}}$$

1st term: Use **partial fractions** (see the Background Info sheet and HWs ## 5 & 7):

$$\frac{6}{s(s-3)} = \frac{A_1}{s} + \frac{A_2}{s-3}, \quad A_1 = -2, \quad A_2 = 2$$

$$\mathcal{L}^{-1}\left\{-\frac{2}{s} + \frac{2}{s-3}\right\} = \underbrace{-2h(t)}_{\text{from Table}} + \underbrace{2h(t)e^{3t}}_{\text{using Thm. 5.4(a)} \text{ and the previous term}}$$

2nd term: as above

$$\mathcal{L}^{-1}\left\{\frac{5}{s-3}\right\} = 5h(t)e^{3t}$$

$$\text{Answer: } y(t) = -2h(t) + \underbrace{2h(t)e^{3t} + 5h(t)e^{3t}}_{7h(t)e^{3t}}$$

$$\text{for } t > 0, \quad h(t) = 1 \quad \Leftrightarrow \quad -2 + 7e^{3t} \quad (t > 0).$$

Ex. 3(b) Same, but for  $f(t) = \begin{cases} 0, & t < 2 \\ 6, & t \geq 2 \end{cases} = 6h(t-2)$ .

Sol'n:

1) Proceed as in 1) of Ex. 3(a); the difference will be only in  $\mathcal{L}\{f(t)\}$ :

$$\mathcal{L}\{f(t)\} = 6 \cdot \frac{e^{-2s}}{s} \quad \text{came from } h(t-2)$$

Table (#14)

or Table (#1) + Thm. 5.4 (b)

27-10

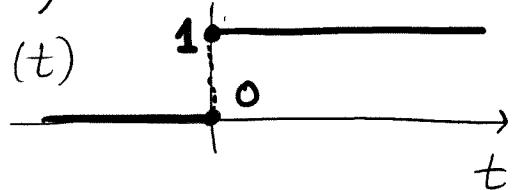

$$2) \quad Y(s) = \frac{1}{s-3} \left( 6 \frac{e^{-2s}}{s} + 5 \right)$$

$$y(t) = \mathcal{L}^{-1} \left\{ e^{-2s} \underbrace{\frac{6}{s(s-3)}}_{\substack{\text{use} \\ \text{Thm. 5.4(6)}}} + \underbrace{\frac{5}{s-3}}_{\substack{\text{from Ex. 3(a)} \\ \text{same as in} \\ \text{Ex. 3(a)}}} \right\}$$

$$h(t-2) \left( -2h(t-2) + 2h(t-2)e^{3(t-2)} \right)$$

$$\text{Now use the fact: } (h(t))^2 = h(t)$$

$$\Rightarrow$$

Answer:  $y(t) = -2h(t-2)(1 - e^{3(t-2)}) + 5e^{3t}h(t).$

Ex. 4 Solve the IVP

$$y'' - y = e^{-2t}, \quad y(0) = y_0, \quad y'(0) = y'_0.$$

Sol'n:

$$1) \quad \mathcal{L}\{y'' - y\} = \mathcal{L}\{e^{-2t}\}$$

$\downarrow$  Thm. 5.5 (6)      Table

$$(s^2 Y(s) - s y_0 - y'_0) - Y(s) = \frac{1}{s+2}$$

$$(s^2 - 1) Y(s) = \frac{1}{s+2} + s y_0 + y'_0$$

$$Y(s) = \frac{1}{s^2 - 1} \cdot \left( \frac{1}{s+2} + s y_0 + y'_0 \right)$$

$\underbrace{s^2 - 1}_{\Phi(s)}$      $\underbrace{\frac{1}{s+2}}_{F(s)}$      $\underbrace{s y_0 + y'_0}_{I(s)}$

See the diagram  
on p. 27-1

$$= \frac{1}{(s^2 - 1)(s+2)} + y_0 \frac{s}{s^2 - 1} + y'_0 \frac{1}{s^2 - 1}$$

27-11

Each of these terms is done by partial fraction expansion:

$$Y(s) =$$

$$\left( \frac{1/6}{s-1} - \frac{1/2}{s+1} + \frac{1/3}{s+2} \right) + y_0 \left( \frac{1/2}{s-1} + \frac{1/2}{s+1} \right) + y'_0 \left( \frac{1/2}{s-1} - \frac{1/2}{s+1} \right)$$

2) Use inverse LT (again, use the Table):

$$y(t) = \left( \frac{1}{6} e^t - \frac{1}{2} e^{-t} + \frac{1}{3} e^{-2t} \right) + \underline{\underline{y'_0}} \left( e^t + e^{-t} \right) + \underline{\underline{y'_0}} \left( e^t - e^{-t} \right).$$
